USE OF A MODULATOR OF AT LEAST ONE RECEPTOR CHOSEN FROM THE IL-8 TYPE B RECEPTOR AND THE PACAP TYPE 1 RECEPTOR, FOR THE PREPARATION OF A PHARMACEUTICAL COMPOSITION FOR TREATING ROSACEA

The present invention relates to the field of treating rosacea. The invention is directed towards providing novel pharmaceutical compositions, more particularly dermatological compositions, which are useful for treating rosacea and comprise as active agent a modulator of at least one receptor chosen from the group comprising the interleukin 8 type B receptor and the PACAP type 1 receptor.

Rosacea is a common, chronic and progressive inflammatory dermatitis associated with vascular instability. It mainly affects the central part of the face and is characterized by redness of the face or hot flushes, facial erythema, papules, pustules and telangiectasia. In serious cases, especially in men, the soft tissue of the nose may swell and produce a bulbous swelling known as rhinophyma.

Rosacea generally occurs between the ages of 25 and 70, and is much more common in people of fair complexion. It more particularly affects women, although this affection is generally more severe in men. Rosacea is chronic and lasts for years with periods of exacerbation and of remission.

Rosacea was originally called "acne rosacea" because its papules (points of slight raising of the skin) and its inflammatory pustules (pus scabs) greatly resemble those of common acne. In contrast with common acne, whose aetiology is based on abnormal keratinization, an increase in sebum production and also bacterial inflammation, the inflammation of rosacea is vascular in nature and is poorly understood. The result of this facial vascular anomaly is a permanent oedema of the

dermis, which may be accompanied by an increased colonization with *Demodex folliculorum*, a mite usually found in the follicles of the face.

According to various studies, *Demodex folliculorum* is thought to have an aetiological role in rosacea (Erbagi et al. 1998, Int. J. Dermatol., vol. 37, pages 421-425; Purcell et al. 1986, J. Am. Acad. Dermatol., vol. 15, pages 1159-1162; Sibenge et al. 1992, J. Am. Acad. Dermatol., vol. 26, pages 590-593). It appears that *Demodex folliculorum* causes or aggravates inflammatory reactions, reflected by papules and pustules, by blocking the pilosebaceous follicles of the face (Roihu et al. 1998, J. Cutan. Pathol., vol. 25, pages 550-552). This parasite is moreover thought to trigger a humoral immune response (Nunzi et al. 1980, Br. J. Dermatol., vol. 103, pages 543-551; Manna et al. 1982, Br. J. Dermatol., vol. 107, pages 203-208).

The pathogenesis of rosacea is poorly understood. Many factors may be involved without necessarily inducing this complaint. They are, for example, psychological factors, gastrointestinal disorders, environmental factors (exposure to sunlight, temperature, humidity), emotional factors (stress), dietary factors (alcohol, spices), hormonal factors or vascular factors, or even infection with *Helicobacter pilori*.

Rosacea develops in four stages, but passage through all the stages is not obligatory:

- stage 1 of vascular relaxation (at about 20 years old). The patients have sudden bursts of paroxystic redness of the face and neck, with a hot sensation, but with no systemic signs. After the attacks, the skin of the face returns to normal. These "flushes" are triggered by changes in temperature (occasionally leading to thermophobia), and the intake of hot drinks or alcohol;

- stage 2 of erythemato-telangiectasia (at about

30 years old). The cheekbone areas are diffusely red. Dilated capillaries constituting standard acne rosacea are observed therein. In contrast with stage 1, the redness is permanent. Besides the cheeks, the chin and the middle of the forehead may be affected;

- stage 3 of papulo-pustules (at about 40 years old). Papules and pustules a few millimetres in diameter develop on a background of erythema, without associated comedones. This dermatitis may be very extensive, occasionally up to the bald part of the scalp in men, but is absent from the area around the mouth and the eyes. The patients complain of sensitive skin, with subjective intolerance to the majority of topical products and greasy cosmetics;

- stage 4 of rhinophyma (at about 50 years old or later). This late phase mainly affects men, in contrast with the other stages. The nose is increased in volume and diffusely red, and the follicular orifices are dilated. The skin gradually thickens.

The minor forms of rosacea may be treated with active agents such as anti-seborrhoeic agents and anti-infectious agents, for example benzoyl peroxide, retinoic acid or metronidazole. Metronidazole, or (2-methyl-5-nitroimidazolyl)-2-ethanol, is known in the prior art for its antibacterial, anti-parasitic and anti-protozoan properties. It exerts selective toxicity towards anaerobic microorganisms and also hypoxic cells. In the latter, metronidazole is reduced to derivatives capable of impairing the DNA structure of these cells.

As regards the most diffuse forms of the complaint, they respond well to general antibiotic therapy with cyclines. However, these treatments have unpleasant side effects for the patient, such as irritation or intolerance phenomena.

Furthermore, on account of the multi-factor aspect of

rosacea, there are a huge number of treatments for this condition, but the search continues for an effective treatment that is without risk for the patient.

The Applicant's studies have demonstrated the usefulness of modulators of receptors chosen from the group comprising the interleukin 8 type B receptor and the PACAP type 1 receptor in the treatment of rosacea.

The interleukin 8 receptors are seven-domain transmembrane receptors and are coupled to G proteins. Two interleukin 8 receptors have been identified, named IL-8RA or CXCR1 and IL-8RB or CXCR2.

PACAP, "pituitary adenylate cyclase-activating peptide", has 68% identity with vasoactive intestinal peptide (VIP), one of the members of the secretin/glucagon/GHRH family. PACAP deploys pleiotropic effects throughout the body during development, but also in adults. It participates in essential functions such as growth, endocrine and digestive activity, cardiovascular and respiratory control, immune responses and circadian rhythm. It binds to and activates a multitude of receptor subtypes, some of which (type II) have the particular feature of also binding VIP with the same high affinity. These receptors are widely distributed in the brain and the peripheral tissues. Among the PACAP receptors, the type 1 receptor, PAC-1 (or PVR1), is known.

PACAP and IL-8 are both involved in inflammation. Specifically, PACAP reduces the release of pro-inflammatory cytokines and inhibits neutrophil activation.

The Applicant's studies have demonstrated the

involvement of receptors chosen from the group comprising the interleukin 8 type B receptor and the PACAP type 1 receptor in the treatment of rosacea. This activity was demonstrated by using metronidazole, which has the consequence of modulating the binding of natural ligands to receptors chosen from the group comprising the IL-8RB receptor and the PAC-1 receptor.

As indicated previously, the invention is directed towards offering a novel method for treating rosacea, which consists in administering to an individual suffering from this pathology an effective amount of a modulator of at least one receptor chosen from the group comprising IL-8RB receptor and the PAC-1 receptor.

Consequently, the invention relates more particularly to the use of a modulator of at least one receptor chosen from the group comprising the IL-8RB receptor and the PAC-1 receptor, for the preparation of a pharmaceutical composition for treating rosacea.

The invention also relates to the use of a modulator of the IL-8RB receptor and the PAC-1 receptor, for the preparation of a pharmaceutical composition for treating rosacea.

According to the present invention, the term "modulator" means any molecule that increases the binding of at least one natural ligand to its receptor, the said receptor being chosen from the group comprising the IL-8RB receptor and the PAC-1 receptor.

More particularly, the pharmaceutical composition that is the subject of the present invention is a dermatological composition for topical application to the skin.

According to the present invention, the term "treating

rosacea" means the treatment and/or prevention of rosacea, at one or more of the stages described above.

According to a first embodiment of the invention, the composition is intended for treating the first stage of rosacea.

According to a second embodiment of the invention, the composition is intended for treating the second stage of rosacea.

According to a third embodiment of the invention, the composition is intended for treating the third stage of rosacea.

According to a fourth embodiment of the invention, the composition is intended for treating the fourth stage of rosacea.

According to a preferential embodiment, the composition contains from 0.0001% to 20% of an antagonist as defined above, preferably from 0.1% to 2% and more preferentially from about 0.75% to 1% of a modulator as defined above, expressed by weight relative to the total weight of the composition.

Needless to say, the present invention concerns, besides the use of a modulator as defined above, the use of derivatives thereof. The term "derivatives" means compounds that differ from a modulator as defined above by substitution, addition or removal of one or more chemical groups.

Advantageously, the compositions of the invention comprise, besides a modulator as defined above, at least one other therapeutic agent capable of increasing the efficacy of the treatment. Non-limiting examples of such agents that may be mentioned include antibiotics, antibacterial agents, antiviral agents, antiparasitic

agents, antifungal agents, anaesthetics, analgesics, antiallergic agents, retinoids, free-radical scavengers, anti-pruriginous agents, keratolytic agents, anti-seborrhoeic agents, antihistamines, sulfides, immunosuppressant products and anti-proliferative products.

According to one particular embodiment of the invention, the modulator is not metronidazole. According to another particular embodiment of the invention, the composition of the present invention also contains metronidazole.

The invention also relates to a process for identifying a modulator of at least one receptor chosen from the group comprising the IL-8RB receptor and the PAC-1 receptor:

a) placing the radiolabelled specific ligand in contact with the human recombinant protein of the PAC-1 and/or IL-8RB receptor in a sample;

b) placing the radiolabelled specific ligand and the non-radiolabelled specific ligand in excess in contact with the human recombinant protein of the receptor in another sample;

c) adding the test compound to the two samples;

d) measuring the radioactivity by scintillation counting in the two samples;

e) calculating the difference in radioactivity measured in the two samples;

f) selecting the said compounds for which an increase in radioactivity is obtained in step e) relative to the control value obtained with the receptors not placed in contact with the test compound.

The compositions of the invention may also comprise any additive usually used in the pharmaceutical or dermatological field that is compatible with a modulator as defined above. Mention may be made especially of sequestrants, antioxidants, sunscreens,

preserving agents, for example DL-α-tocopherol, fillers, electrolytes, humectants, dyes, common mineral or organic acids or bases, fragrances, essential oils, cosmetic active agents, moisturizers, vitamins, essential fatty acids, sphingolipids, self-tanning compounds such as DHA, skin calmative and protective agents such as allantoin, pro-penetrating agents and gelling agents. Needless to say, a person skilled in the art will take care to select this or these optional additional compound(s), and/or the amount thereof, such that the advantageous properties of the composition according to the invention are not, or are not substantially, adversely affected.

These additives may be present in the composition in a proportion of from 0 to 20% by weight relative to the total weight of the composition.

Examples of sequestrants that may be mentioned include ethylenediaminetetraacetic acid (EDTA), and also derivatives or salts thereof, dihydroxyethylglycine, citric acid and tartaric acid, or mixtures thereof.

Examples of preserving agents that may be mentioned include benzalkonium chloride, phenoxyethanol, benzyl alcohol, diazolidinylurea and parabens, or mixtures thereof.

Examples of humectants that may be mentioned include glycerol and sorbitol.

The compositions of the invention may contain one or more pro-penetrating agents in preferential concentrations ranging from 0 to 20% and more preferentially ranging from 0.6% to 3% by weight relative to the total weight of the composition. Among the pro-penetrating agents that are preferentially used, without this list being limiting, are compounds such as propylene glycol, dipropylene glycol, propylene

glycol dipelargonate, lauroglycol and ethoxydiglycol.

Advantageously, the compositions according to the invention may also contain one or more wetting liquid surfactants in preferential concentrations ranging from 0 to 10% and more preferentially ranging from 0.1% to 2%.

The compositions of the present invention may be in any galenical form normally used for topical application, especially in the form of aqueous, aqueous-alcoholic or oily solutions, dispersions of the lotion type, aqueous, anhydrous or lipophilic gels, emulsions of liquid or semi-liquid consistency of the milk type, obtained by dispersing a fatty phase in an aqueous phase (O/W) or, conversely, (W/O), or suspensions or emulsions of soft, semi-solid or solid consistency of the cream, gel or ointment type, or alternatively microemulsions, microcapsules, microparticles or vesicular dispersions of ionic and/or nonionic type.

Preferably, the creams may be formulated from a mixture of mineral oil or from a mixture of beeswax and of water, which emulsifies instantaneously, to which is added the modulator as defined above, dissolved in a small amount of oil such as almond oil.

The ointments may be formulated by mixing a solution of the said modulator in an oil such as almond oil in warmed paraffin, followed by leaving the mixture to cool.

As examples of compositions according to the invention, mention may be made of those comprising an active phase containing (expressed as weight percentages):

- 0 to 90%, preferentially 5% to 25% and especially 10% to 20% of water;
- 0 to 10%, preferentially 0 to 2% and especially 0 to 0.5% of wetting liquid surfactant;

- 0 to 20%, preferentially 0 to 10% and especially 2% to 5% of pro-penetrating agent;

- 0.0001% to 20% and preferentially 0.1% to 2% of a modulator as defined above;

and an aqueous phase comprising a pH-independent gelling agent, and water.

The aqueous phase of a composition according to the invention in the form of an emulsion may comprise water, a floral water such as cornflower water or a natural spring or mineral water chosen, for example, from eau de Vittel, the waters of the Vichy basin, eau d'Uriage, eau de la Roche Posay, eau de la Bourboule, eau d'Enghien-les-Bains, eau de Saint Gervais-les-Bains, eau de Néris-les-Bains, eau d'Allevard-les-Bains, eau de Digne, eau de Maizières, eau de Neyrac-les-Bains, eau de Lons-le-Saunier, les Eaux Bonnes, eau de Rochefort, eau de Saint Christau, eau des Fumades, eau de Tercis-les-Bains, eau d'Avène and eau d'Aix-les-Bains.

The said aqueous phase may be present in a content of between 10% and 90% by weight and preferably between 20% and 80% by weight relative to the total weight of the composition.

Non-limiting examples that may be mentioned include gelling agents of the polyacrylamide family such as the sodium acryloyldimethyltaurate copolymer/isohexadecane/polysorbate-80 mixture sold under the name Simulgel 600 by the company SEPPIC, the polyacrylamide/C13-14 isoparaffin/laureth-7 mixture, for instance the product sold under the name Sepigel 305 by the company SEPPIC, the family of acrylic polymers coupled to hydrophobic chains, such as the PEG-150/decyl/SMDI copolymer sold under the name Aculyn 44 (polycondensate comprising at least, as components, a polyethylene glycol containing 150 or 180 mol of ethylene oxide, decyl alcohol and methylenebis(4-

cyclohexyl isocyanate) (SMDI), at 35% by weight in a mixture of propylene glycol (39%) and water (26%)), and the family of modified starches such as the modified potato starch sold under the name Structure Solanace, or mixtures thereof.

The preferred gelling agents are derived from the polyacrylamide family, such as Simulgel 600 or Sepigel 305 or mixtures thereof.

The gelling agent as described above may be used in preferential concentrations ranging from 0.1% to 15% and more preferentially ranging from 0.5% to 5%.

The gels may preferably be prepared by dispersing or dissolving the modulator as defined above in a suitable ratio in a gel of carbomer, poloxamer or cellulose-based type.

Other advantages and characteristics of the invention will emerge from the examples below concerning the activity of metronidazole as a modulator of receptors chosen from the group comprising the PAC-1 receptor and the IL-8RB receptor.

Example 1 - Measurement of the binding to the IL-8RB and PAC-1 receptors

1) Protocol:

The test of binding to the PAC-1 receptor was performed according to the protocol described by Cauvin et al., 1991, Regul Peptides, vol. 35, pages 161-173.

The test of binding to the IL-8RB receptor was performed according to the protocol described by White et al., 1998, J Biol Chem, vol. 273, pages 10095-10098.

2) Experimental conditions:

The binding of metronidazole to each receptor was determined by competitive experiments. The receptor, human recombinant protein, was incubated for times indicated in Table 1 below, with a simple concentration of radiolabelled specific ligand, in the presence of 10 μM metronidazole. The bound radioactivity was measured by scintillation counting.

Table 1

Receptor	Radiolabelled specific ligand	Non-specific ligand	Incubation conditions
IL-8RB	[^{125}I]IL-8 (0.2 nM)	IL-8 (0.3 μM)	60 min / 22°C
OAC-1	[^{125}I]PACAP$_{1-27}$ (0.2 nM)	PACAP$_{1-27}$ (0.1 μM)	30 min / 37°C

3) Analysis and expression of the results:

The specific binding of the ligand to the receptor is defined as the difference between the total binding and the non-specific binding determined in the presence of an excess of unlabelled ligand.

The results are expressed in Table 2 below as a percentage of control specific binding and as a percentage of inhibition of the control specific binding obtained in the presence of metronidazole.

Table 2

Receptor	Metronidazole (μM)	% of control specific binding (± SD)
IL-8RB	10	120.8+/-0.7
PAC-1	10	133.2 +/-13.2

Metronidazole thus induces the binding of the ligand to its IL-8RB receptor and to the PCA-1 receptor.
